THE CREATIVITY CRISIS

FOR THE FIRST TIME, RESEARCH SHOWS THAT AMERICAN CREATIVITY IS DECLINING. WHAT WENT WRONG—AND HOW WE CAN FIX IT.

BY PO BRONSON
AND ASHLEY MEHRMANN
Back in 1958, Ted Schwarzrock was an 8-year-old third grader when he became one of the “Torrance kids,” a group of nearly 400 Minneapolis children who completed a series of creativity tasks newly designed by professor E. Paul Torrance. Schwarzrock still vividly remembers the moment when a psychologist handed him a fire truck and asked, “How could you improve this toy to make it better and more fun to play with?” He recalls the psychologist being excited by his answers. In fact, the psychologist’s session notes indicate Schwarzrock rattled off 25 improvements, such as adding a removable ladder and springs to the wheels. That wasn’t the only time he impressed the scholars, who judged Schwarzrock to have “unusual visual perspective” and “an ability to synthesize diverse elements into meaningful products.”

The accepted definition of creativity is production of something original and useful, and that’s what's reflected in the tests. There is never one right answer. To be creative requires divergent thinking (generating many unique ideas) and then convergent thinking (combining those ideas into the best result).

In the 50 years since Schwarzrock and the others took their tests, scholars—first led by Torrance, now his colleague, Garnet Millar—have been tracking the children, recording every patent earned, every business founded, every research paper published, and every grant awarded. They tallied the books, dances, radio shows, art exhibitions, software programs, advertising campaigns, hardware innovations, music compositions, public policies (written or implemented), leadership positions, invited lectures, and buildings designed.

Nobody would argue that Torrance’s tasks, which have become the gold standard in creativity assessment, measure creativity perfectly. What’s shocking is how incredibly well Torrance’s creativity index predicted those kids’ creative accomplishments as adults. Those who came up with more good ideas on Torrance’s tasks grew up to be entrepreneurs, inventors, college presidents, authors, doctors, diplomats, and software developers. Jonathan Plucker of Indiana University recently reanalyzed Torrance’s data. The correlation to lifetime creative accomplishment was more than three times stronger for childhood creativity than childhood IQ.

Like intelligence tests, Torrance’s test—a 90-minute series of discrete tasks, administered by a psychologist—has been taken by millions worldwide in 50 languages. Yet there is one crucial difference between IQ and CQ scores. With intelligence, there is a phenomenon called the Flynn effect—each generation, scores go up about 10 points. Enriched environments are making kids smarter. With creativity, a reverse trend has just been identified and is being reported for the first time here: American creativity scores are falling.

Kyung Hee Kim at the College of William & Mary discovered this in May, after analyzing almost 900,000 Torrance scores of children and adults. Kim found creativity scores had been steadily rising, just like IQ scores, until 1990. Since then, creativity scores have consistently inched downward. “It’s very clear, and the decrease is very significant,” Kim says. It is the scores of younger children in America—from kindergarten through sixth grade—for whom the decline is “most serious.”

The potential consequences are sweeping. The necessity of human ingenuity is undisputed. A recent IBM poll of 1,500 CEOs identified creativity as the No. 1 “leadership competency” of the future. Yet it’s not just about sustaining our nation’s economic growth. All around us are matters of national and international importance that are crying out for creative solutions, from saving the Gulf of Mexico to bringing peace to Afghanistan to delivering health care. Such solutions emerge from a healthy marketplace of ideas, sustained by a populace constantly contributing original ideas and receptive to the ideas of others.

It’s too early to determine conclusively why U.S. creativity scores are declining. One likely culprit is the number of hours kids now spend in front of the TV and playing videogames rather than engaging in creative activities. Another is the lack of creativity development in our schools. In effect, it’s left to the luck of the draw who becomes creative: there’s no concerted effort to nurture the creativity of all children.

Around the world, though, other countries are making creativity development a national priority. In 2008 British secondary-school curricula—from science to foreign language—was revamped to emphasize idea generation, and pilot programs have begun using Torrance’s test to assess their progress. The European Union designated 2009 as the European Year of Creativity and Innovation, holding conferences on the neuroscience of creativity, financing teacher training, and instituting problem-based learning programs—curricula driven by real-world inquiry—for both children and adults. In China there has been widespread education reform to extinguish the drill-and-kill teaching style. Instead, Chinese schools are also adopting a problem-based learning approach.

Plucker recently toured a number of such schools in Shanghai and Beijing. He was amazed by a boy who, for a class science project, rigged a tracking device for his moped with parts from a cell phone. When faculty of a major Chinese university asked Plucker to identify trends in American education, he described our focus on standardized curriculum,rote memorization, and nationalized testing. “After my answer
was translated, they just started laughing out loud,” Plucker says. “They said, ‘You’re racing toward our old model. But we’re racing toward your model, as fast as we can.’”

Overwhelmed by curriculum standards, American teachers warn there’s no room in the day for a creativity class. Kids are fortunate if they get an art class once or twice a week. But to scientists, this is a non sequitur, borne out of what University of Georgia’s Mark Runco calls “art bias.” The age-old belief that the arts have a special claim to creativity is unfounded. When scholars gave creativity tasks to both engineering majors and music majors, their scores laid down on an identical spectrum, with the same high averages and standard deviations. Inside their brains, the same thing was happening—ideas were being generated and evaluated on the fly.

Researchers say creativity should be taken out of the art room and put into homeroom. The argument that we can’t teach creativity because kids already have too much to learn is a false tradeoff. Creativity isn’t about freedom from concrete facts. Rather, fact-finding and deep research are vital stages in the creative process. Scholars argue that current curriculum standards can still be met, if taught in a different way.

To understand exactly what should be done requires first understanding the new story emerging from neuroscience. The lore of pop psychology is that creativity occurs on the right side of the brain. But we now know that if you tried to be creative using only the right side of your brain, it’d be like living with ideas perpetually at the tip of your tongue, just beyond reach.

When you try to solve a problem, you begin by concentrating on obvious facts and familiar solutions, to see if the answer lies there. This is a mostly left-brain stage of attack. If the answer doesn’t come, the right and left hemispheres of the brain activate together. Neural networks on the right side scan remote memories that could be vaguely relevant. A wide range of distant information that is normally tuned out becomes available to the left hemisphere, which searches for unseen patterns, alternative meanings, and high-level abstractions.

Having glimpsed such a connection, the left brain must quickly lock in on it before it escapes. The attention system must radically reverse gears, going from defocused attention to extremely focused attention. In a flash, the brain pulls together these disparate shards of thought and binds them into a new single idea that enters consciousness. This is the “aha!” moment of insight, often followed by a spark of pleasure as the brain recognizes the novelty of what it’s come up with.

Now the brain must evaluate the idea it just generated. Is it worth pursuing? Creativity requires constant shifting, blander pulses of both divergent thinking and convergent thinking, to combine new information with old and forgotten ideas. Highly creative people are very good at marshaling their brains into bilateral mode, and the more creative they are, the more they dual-activate.

Is this learnable? Well, think of it like basketball. Being tall does help to be a pro basketball player, but the rest of us can still get quite good at the sport through practice. In the same way, there are certain innate features of the brain that make some people naturally prone to divergent thinking. But convergent thinking and focused attention are necessary, too, and those require different neural gifts. Crucially, rapidly shifting between these modes is a top-down function under your mental control. University of New Mexico neuroscientist Rex Jung has concluded that those who diligently practice creative activities learn to recruit their brains’ creative networks quicker and better. A lifetime of consistent habits gradually changes the neurological pattern.

A fine example of this emerged in January of this year, with release of a study by University of Western Ontario neuroscientist Daniel Ansari and Harvard’s Aaron Berkowitz, who studies music cognition. They put Dartmouth music majors and nonmusicians in an fMRI scanner, giving participants a one-handed fiber-optic keyboard to play melodies on. Sometimes melodies were rehearsed; other times they were creatively improvised. During improvisation, the highly trained music majors used their brains in a way the nonmusi-
WHAT DOES CREATIVITY LOOK LIKE?
We asked volunteers to create drawings from incomplete figures. James C. Kaufman of California State University, San Bernardino, and Kyung Hee Kim of the College of William & Mary evaluated their work.

YOEL, CHILD
Kim gave Yoel 17 out of 20 points. "Bonus points for motion and for not using the boundaries," Kaufman said.

BILL, ADULT
Kaufman gave "mega-points for humor," and saw a sense of movement and action. Kim gave Bill 18 out of 20 points.

GRACE, CHILD
Kim gave this 17 out of 20 points for expressiveness and vividness. Kaufman saw "a lot of detail, a lot of stuff going on."

JOSHUA, ADULT
Kaufman noted unique visual perspective. Kim gave 15 out of 18 points; breaking the boundary was Joshua's strength.

GALILEE, CHILD
Kaufman called this "pretty good." Kim thought it showed that Galilee is precise and careful in thinking.

JONATHAN, ADULT
The figure isn't really integrated into the drawing, Kaufman said. Kim gave it only 4 out of 18 points.

around. They lost interest because they stopped asking questions.

Having studied the childhoods of highly creative people for decades, Claremont Graduate University's Mihaly Csikszentmihalyi and University of Northern Iowa's Gary G. Gute found highly creative adults tended to grow up in families embodying opposites. Parents encouraged uniqueness, yet provided stability. They were highly responsive to kids' needs, yet challenged kids to develop skills. This resulted in a sort of adaptability: in times of anxiousness, clear rules could reduce chaos—yet when kids were bored, they could seek change, too. In the space between anxiety and boredom was where creativity flourished.

It's also true that highly creative adults frequently grew up with hardship. Hardship by itself doesn't lead to creativity, but it does force kids to become more flexible—and flexibility helps with creativity.

In early childhood, distinct types of free play are associated with high creativity. Preschoolers who spend more time in role-play (acting out characters) have higher measures of creativity; voicing someone else's point of view helps develop their ability to analyze situations from different perspectives. When playing alone, highly creative first graders may act out strong negative emotions: they'll be angry, hostile, anguished. The hypothesis is that play is a safe harbor to work through forbidden thoughts and emotions.

In middle childhood, kids sometimes create paracosms—fantasies of entire alternative worlds. Kids revisit their paracosms repeatedly, sometimes for months, and even create languages spoken there. This type of play peaks at age 9 or 10, and it's a very strong sign of future creativity. A Michigan State University study of MacArthur "genius award" winners found a remarkably high rate of paracose creation in their childhoods.

From fourth grade on, creativity no longer occurs in a vacuum; researching
and studying become an integral part of coming up with useful solutions. But this transition isn’t easy. As school stuffs more complex information into their heads, kids get overloaded, and creativity suffers. When creative children have a supportive teacher—someone tolerant of unconventional answers, occasional disruptions, or detours of curiosity—they tend to excel. When they don’t, they tend to underperform and drop out of high school or don’t finish college at high rates.

They’re quitting because they’re discouraged and bored, not because they’re dark, depressed, anxious, or neurotic. It’s a myth that creative people have these traits. (Those traits actually shut down creativity; they make people less open to experience and less interested in novelty.) Rather, creative people, for the most part, exhibit active moods and positive affect. They’re not particularly happy—contentment is a kind of complacency creative people rarely have. But they’re engaged, motivated, and open to the world.

The new view is that creativity is part of normal brain function. Some scholars go further, arguing that lack of creativity—not having loads of it—is the real risk factor. In his research, Runco asks college students, “Think of all the things that could interfere with graduating from college.” Then he instructs them to pick one of those items and come up with as many solutions for that problem as possible. This is a classic divergent-convergent creativity challenge. A subset of respondents, like the proverbial Murphy, quickly list every imaginable way things can go wrong. But they demonstrate a complete lack of flexibility in finding creative solutions. It’s this inability to conceive of alternative approaches that leads to despair. Runco’s two questions predict suicide ideation—even when controlling for pre-existing levels of depression and anxiety.

In Runco’s subsequent research, those who do better in both problem-finding and problem-solving have better relationships. They are more able to handle stress and overcome the bumps life throws in their way. A similar study of 1,500 middle schoolers found that those high in creative self-efficacy had more confidence about their future and ability to succeed. They were sure that their ability to come up with alternatives would aid them, no matter what problems would arise.

When he was 30 years old, Ted Schwarzrock was looking for an alternative. He was hardly on track to becoming the prototype of Torrance’s longitudinal study. He wasn’t artistic when young, and his family didn’t recognize his creativity or nurture it. The son of a dentist and a speech pathologist, he had been pushed into medical school, where he felt stifled and commonly had run-ins with professors and bosses. But eventually, he found a way to combine his creativity and medical expertise: inventing new medical technologies.

Today, Schwarzrock is independently wealthy—he founded and sold three medical-products companies and was a partner in three more. His innovations in health care have been wide ranging, from a portable respiratory oxygen device to skin-absorbing anti-inflammatory to insights into how bacteria become antibiotic-resistant. His latest project could bring down the cost of spine-surgery implants 50 percent. "As a child, I never had an identity as a ‘creative person,’" Schwarzrock recalls. "But now that I know, it helps explain a lot of what I felt and went through.”

Creativity has always been prized in American society, but it’s never really been understood. While our creativity scores decline unchecked, the current national strategy for creativity consists of little more than praying for a Greek muse to drop by our houses. The problems we face now, and the future, simply demand that we do more than just hope for inspiration to strike. Fortunately, the science can help: we know the steps to lead that elusive muse right to our doors. □

IT’S LEFT TO THE LUCK OF THE DRAW WHO BECOMES CREATIVE: THERE’S NO CONCERTED EFFORT TO NURTURE THE CREATIVITY OF ALL CHILDREN.

TEST YOUR CREATIVITY

Just suppose...we could transport ourselves anywhere we want with just a twitch of the nose or blink of the eye. What would be some problems, benefits, etc., of this situation? You have three minutes to answer.

Scorers look for a high number of responses and the ability to simultaneously pursue different lines of thought.

BRAINSTORMING IN A GROUP BECAME POPULAR IN 1953 WITH THE PUBLICATION
of a business book, *Applied Imagination*. But it’s been proven not to
work since 1958, when Yale researchers found that the technique actually
reduced a team’s creative output: the same number of people generate
more and better ideas separately than together. In fact, according to Uni-
versity of Oklahoma professor Michael Mumford, half of the commonly
used techniques intended to spur creativity don’t work, or even have a
negative impact. As for most commercially available creativity train-
ing, Mumford doesn’t mince words: it’s “garbage.” Whether for adults or
kids, the worst of these programs focus solely on imagination exercises,
expression of feelings, or imagery. They pander to an easy, unchallenging
notion that all you have to do is let your natural creativity out of its shell.
However, there are some techniques that do boost the creative process:

**DON’T TELL SOMEONE TO ‘BE CREATIVE.’**

Such an instruction may just cause people to freeze up. However, accord-
ing to the University of Georgia’s Mark Runco, there is a suggestion that works:
“Do something only you would come up with—that none of your friends or fam-
ily would think of.” When Runco gives this advice in experiments, he sees the
number of creative responses double.

**REDUCE SCREEN TIME.**

According to University of Texas professor Elizabeth Vand-
water, for every hour a kid regularly watches television, his overall time in
creative activities—from fantasy play to arts projects—drops as much as 11 percent.
With kids spending about three hours in front of televisions each day, that could
be a one-third reduction in creative time—less time to develop a sense of
creative self-efficacy through play.

**GET MOVING.**

Almost every dimension of cognition improves from 30 min-
utes of aerobic exercise, and creativity is no exception. The type of exercise
doesn’t matter and the boost lasts for at least two hours afterward. However,
there’s a catch: this is the case only for the physically fit. For those who rarely
exercise, the fatigue from aerobic activity counteracts the short-term benefits.

**FOLLOW A PASSION.**

Rena Subotnik, a researcher with the American Psychological Associa-
tion, has studied children’s progression
into adult creative careers. Kids do best when
they are allowed to develop deep passions and
pursue them wholeheartedly—at the expense of
well-roundedness. “Kids who have deep
identification with a field have better discipline
and handle setbacks better,” she noted. By
contrast, kids given superficial exposure to
many activities don’t have the same centeredness to overcome
periods of difficulty.

**TAKA BREAK.**

Those who study multi-
tasking report that you can’t
work on two projects simultane-
ously, but the dynamic is different when
you have more than one creative project to
complete. In that situation, more projects get
completed on time when you allow yourself to
switch between them if solutions don’t come
immediately. This corroborates surveys show-
ing that professors who set papers aside to
incubate ultimately publish more papers.
Similarly, preeminent mathematici-
cians usually work on more than
one proof at a time.

**DITCH THE SUGGESTION BOX.**

If you want to increase innovation
within an organization, one of the first
things to do is tear out the suggestion box,
advises Isaac Getz, professor at ESSEC Europe
Business School in Paris. Formalized suggestion
protocols, whether a box on the wall, an e-mailed
form, or an internal Web site, actually stifle
innovation because employees feel that their
ideas go into a black hole of bureaucracy. Instead,
employees need to be able to put their own ideas
into practice. One of the reasons that Toyota’s
manufacturing plant in Georgetown, Ky., is so successful is that it implements
up to 99 percent of employees’ ideas.

**EXPLORE OTHER CULTURES.**

Five experiments by North-
western’s Adam Galinsky showed that
those who have lived abroad outper-
form others on creativity tasks. Creativity is also
higher on average for first- or second-generation
immigrants and bilinguals. The theory is that
cross-cultural experiences force people to adapt
and be more flexible. Just studying another
culture can help. In Galinsky’s lab, people
were more creative after watching a slide
show about China: a 45-minute
session increased creativity
scores for a week.
